1 Assignment 1 (3 points)

1.1 Question 1.1

```
rng_runif = function(a, m, x_zero, nmax) {
  if (!(a >= 0 && a < m)) stop("a in [0, m) is required")
  if (nmax%1 != 0) stop("nmax has to be an integer")

  storage = vector(mode = "numeric", length = nmax+1)
  storage[1] = x_zero

  for (i in 1:(nmax-1)) {
    storage[i+1] = ((a * storage[i]) %% m)
  }

  return(storage[2:length(storage)]/m)
}</pre>
```

1.2 Question 1.2

```
prs_1 = rng_runif(69069, 2^32, 9999, 10000)
prs_2 = rng_runif(630360016, (2^32-1), 690690, 10000)
prs_3 = rng_runif(742938285, (2^32-1), 690690, 10000)
prs_4 = rng_runif(1226874153, (2^32-1), 690690, 10000)
unif_samples = runif(10000)
```

```
a = 69069 and b = 2^32
                                                      a = 630360016 and b = 2^32 - 1

Answer: We see that the second and the last settings have a low-p value and have to be rejected at a
significance level of \alpha = 10\%
  • a = 1 mod p for every prime divisor p of m
  • a = 1 \mod 4 if 4 \text{ divides } m
  • c and m have to be relatively prime (no common divisirs bar 2)
```

1.3 Question 1.3

In our case c = 1.

```
rng_rnorm = function(n, a, m) {
    if (!(a >= 0 && a < m)) stop("a in [0, m) is required")

    n_half = ceiling(n/2)

    storage = vector(mode = "numeric", length = n)

    storage_theta = rng_runif(a = a, m = m, x_zero = 123456789, nmax = n_half) * 2 * pi
    storage_d = rng_runif(a = a, m = m, x_zero = 12345, nmax = n_half)

for (i in 1:n_half) {
        storage[2*i] = sqrt(-2 * log(storage_d[i])) * cos(storage_theta[i])
        storage[2*i+1] = sqrt(-2 * log(storage_d[i])) * sin(storage_theta[i])
    }

    return(storage)
}

rng_normal_1 = rng_rnorm(10000, a = 69069, m =2^32)
rng_normal_2 = rng_rnorm(10000, a = 630360016, m = 2^32-1)

2 Assignment 2

2.1 Question 2.1

```
interpolate = function(A, X, func, gradient = NULL) {

# Interpolation function which is so be used
f_tilde = function(x, a0, a1, a2) a0 + a1 * x + a2 * x^2

# Error function, here MSE
f_error = function(A, X. = X, func. = func) {
    return(sum((func.(X.) - f_tilde(X., A.[1], A.[2], A.[3]))^2))
}

#f_diff = function(A, func) {
    # interpolation = a0 + a1 * x + a2 * x^2
    # error = sum((interpolation - func(X))^2)
# return(error)

#}

# Optimize f_error for parameters in A
res = optim(A, f_error, gradient, method = "BFGS")

# Now define with optimized parameters
f_tilde = function(x) res$par[1] + res$par[2] * x + res$par[3] * x^2
```

```
# Return parameters and function
return(list(A = res$par, f_tilde = f_tilde))
}
```

2.2 Question 2.2

```
f approximate = function(func target, bins, A init, func target gradient = NULL) {
  # Initialize interval length and return matrix
 upper_boundary = 0
  interval_length = 1/bins
  res = matrix(0, nrow = bins, ncol = 5)
  colnames(res) = c("lower_boundary", "upper_boundary", "a0", "a1", "a2")
  # Approximate for each bin
  for (i in 1:bins) {
   lower_boundary = upper_boundary
   upper_boundary = lower_boundary + interval_length
    # We rely on three known points
    #known_values = c(func_target(lower_boundary),
                   func_target((lower_boundary + upper_boundary)/2),
    #
                    func_target(upper_boundary))
   known_values = c(lower_boundary, (lower_boundary + upper_boundary)/2,
                     upper_boundary)
    # Now we optimize for this interval using the previous function
    interpolated = interpolate(func = func_target, X = known_values, A = A_init,
                              gradient = func_target_gradient)$A
    # And fill in the matrix with all necesarry values
   res[i, 1] = lower_boundary
   res[i, 2] = upper_boundary
    res[i, 3:5] = interpolated
  return(res)
```

2.3 Question 2.3

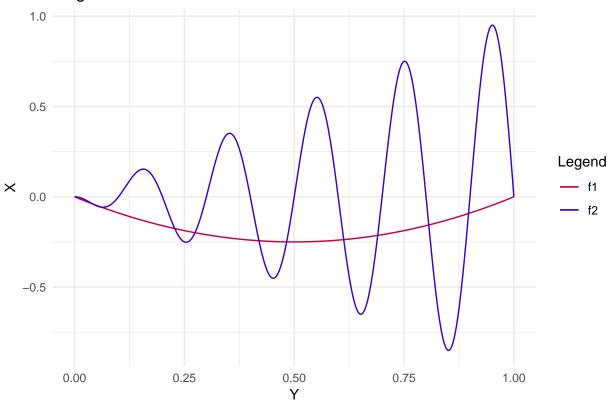

Definition of the original functions.

```
f1 = function(x) -x * (1 - x)

f2 = function(x) -x * sin(10 * pi * x)
```

The look like the following.

Now we perform the interpolation.

```
f1 \text{ res} = f \text{ approximate}(f1, \text{ bins} = 1000, \text{ rep}(0.000, 3))
head(f1_res)
        lower boundary upper boundary
